

Practice Quiz: Conditionals

TOTAL POINTS 5

1. What's the value of this Python expression: `(2**2) == 4`?

1 / 1 point

- ☐ 4
- ☐ `2**2`
- ☒ True
- ☐ False

**Correct**

You nailed it! The conditional operator `==` checks if two values are equal. The result of that operation is a boolean: either True or False.

2. Complete the script by filling in the missing parts. The function receives a name, then returns a greeting based on whether or not that name is "Taylor".

1 / 1 point

```
1 def greeting(name):
2     if name == "Taylor":
3         return "Welcome back Taylor!"
4     else:
5         return "Hello there, " + name
6
7 print(greeting("Taylor"))
8 print(greeting("John"))
```

[Run](#)[Reset](#)

```
Welcome back Taylor!
Hello there, John
```

**Correct**

Great work! You're getting the hang of conditionals in Python.

3. What's the output of this code if number equals 10?

1 / 1 point

```
1  if number > 11:
2      print(0)
3  elif number != 10:
4      print(1)
5  elif number >= 20 or number < 12:
6      print(2)
7  else:
8      print(3)
```

**Correct**

Right on! Our number is 10, which is smaller than 12, so it matches that condition.

4. Is "A dog" smaller or larger than "A mouse"? Is 9999+8888 smaller or larger than 100*100? Replace the plus sign in the following code to let Python check it for you and then answer. 1 / 1 point

```
4      print("A dog is smaller than A mouse ")
5
6      if (9999+8888) > (100*100):
7          print ("9999+8888 is larger than 100*100")
8      else:
```

[Run](#)[Reset](#)

```
A dog is smaller than A mouse
9999+8888 is larger than 100*100
```

- ☐ "A dog" is larger than "A mouse" and 9999+8888 is larger than 100*100
- ☒ "A dog" is smaller than "A mouse" and 9999+8888 is larger than 100*100
- ☐ "A dog" is larger than "A mouse" and 9999+8888 is smaller than 100*100
- ☐ "A dog" is smaller than "A mouse" and 9999+8888 is smaller than 100*100

**Correct**

You got it! Keep getting Python to do the work for you.

5.

1 / 1 point

If a filesystem has a block size of 4096 bytes, this means that a file comprised of only one byte will still use 4096 bytes of storage. A file made up of 4097 bytes will use $4096 * 2 = 8192$ bytes of storage. Knowing this, can you fill in the gaps in the `calculate_storage` function below, which calculates the total number of bytes needed to store a file of a given size?

```
1  def calculate_storage(filesize):
2      block_size = 4096
3      # Use floor division to calculate how many blocks are fully occupied
4      full_blocks = filesize // block_size
5      # Use the modulo operator to check whether there's any remainder
6      partial_block_remainder = filesize % block_size
7      # Depending on whether there's a remainder or not, return
8      # the total number of bytes required to allocate enough blocks
9      # to store your data.
10     if partial_block_remainder > 0:
11         return (full_blocks+1)*block_size
12     return full_blocks*block_size
13
14     print(calculate_storage(1))    # Should be 4096
15     print(calculate_storage(4096)) # Should be 4096
16     print(calculate_storage(4097)) # Should be 8192
17     print(calculate_storage(6000)) # Should be 8192
```

[Run](#)[Reset](#)

```
4096
4096
8192
8192
```

**Correct**

Awesome! Those were some complicated calculations that you needed to do, but you did it!
